Abstract The purpose of this study was to examine the effects of a 6-week training program on the psychophysiological responses of young adults during a simulated military task. Twenty-four participants were randomly assigned to either a control group or a training group. The control group performed the task without any training, while the training group underwent a 6-week training program before performing the task. The results showed that the training group had significantly lower heart rate, blood pressure, and skin temperature compared to the control group during the task. These findings suggest that a 6-week training program can effectively reduce physiological stress responses in young adults during a simulated military task.

Abstract The purpose of this study was to determine whether there were differences in the prevalence of self-reported depression between men and women who had been exposed to violence by intimate partners. Data from the National Longitudinal Study of Women's Health are used to examine the relationship between exposure to partner violence and self-reported depression among 67,000 women aged 18–49 years. Results indicate that women who reported being physically or sexually abused by their current or former partners were more likely than nonabused women to report having experienced depression during the past year. This association remained significant after controlling for other factors associated with depression.
